6. Do not extend pipe block-outs into the base when base is not monolithic with the inlet walls.

7. Locate pipe or pipes, as indicated, with the inlet bottom shaped to channel the flow toward the outlet.

8. Place precast inlet boxes on a properly prepared base as shown in detail B.

9. Construct inlets that exceed 5 feet in height with steps similar to manholes.

10. Place reinforcing barstes, minimum 12 inches long, spaced at 12 inches center to center, as dowels between the inlet base and walls when the concrete walls and inlet base are not constructed monolithically. The dowels may be eliminated if the alternate joint shown in detail A is constructed.

11. Brick or concrete block inlets shall not be permitted.

12. All inlets for pipes > 36 inches in diameter shall have expanded type inlet box, design of which shall be approved by the township engineer.

13. Construct in accordance with PennDOT specifications.

14. Storm sewer drop connections from invert of outflow pipe to invert of inflow pipe shall be a maximum of 2 feet.

OUTLET PROTECTION (MAXIMUM TAILWATER CONDITIONS)
Description

Bioretention is a method of treating stormwater by pooling water on the surface and allowing filtering and settling of suspended solids and sediment at the mulch layer, prior to entering the plants/soil/microbe complex media for infiltration and pollutant removal. Bioretention techniques are used to accomplish water quality improvements and water quantity reduction.

Bioretention can be integrated into a site with a high degree of flexibility and can balance nicely with other structural management systems, including porous asphalt parking lots, infiltration trenches, as well as non-structural stormwater BMPs described in Chapter 5 of the Pennsylvania BMP Manual.

The vegetation serves to filter (water quality) and transpire (water quantity) runoff, and the root systems can enhance infiltration. The plants take up pollutants; the soil medium filters out pollutants and allows storage and infiltration of stormwater runoff; and the bed provides additional volume control. Properly designed bioretention techniques mimic natural ecosystems through species diversity, density, and distribution of vegetation, and the use of native species, resulting in a system that is resistant to insects, disease, pollution, and climatic stresses.

Rain Gardens / Bio-retention Function to:

- Reduce run-off volume.
- Filter pollutants, through both soil particles (which trap pollutants) and plant material (which take up pollutants).
- Recharge groundwater by infiltration.
- Reduce stormwater temperature impacts.
- Enhance evapotranspiration.
- Enhance aesthetics.
- Provide habitat.
